

## L16-PROCESS SYNCHRONIZATION- CRITICAL SECTION

# Session Outline

- ❖ **Background**
- ❖ **The Critical-Section Problem**
- ❖ **Peterson's Solution**

# Objectives of Process Synchronization

- ❖ To introduce the concept of process synchronization.
- ❖ To introduce the critical-section problem, whose solutions can be used to ensure the consistency of shared data
- ❖ To present both software and hardware solutions of the critical-section problem
- ❖ To examine several classical process-synchronization problems
- ❖ To explore several tools that are used to solve process synchronization problems

# Background

- ❖ Processes can execute concurrently
  - ❖ May be interrupted at any time, partially completing execution
- ❖ Concurrent access to shared data may result in data inconsistency
- ❖ Maintaining data consistency requires mechanisms to ensure the orderly execution of cooperating processes

# Producer-Consumer Problem

- ❖ Paradigm for cooperating processes, producer process produces information that is consumed by a consumer process
  - ❖ **unbounded-buffer** places no practical limit on the size of the buffer
  - ❖ **bounded-buffer** assumes that there is a fixed buffer size

# Bounded-Buffer – Producer & Consumer

```
item buffer[BUFFER_SIZE]; int in = 0; int out = 0;
```

## Producer

```
item next_produced;

while (true)

{
    /* produce an item in next
    produced */

    while(((in + 1)% BUFFER_SIZE)
    == out)

        ; /* do nothing */

    buffer[in] = next_produced;

    in = (in + 1) % BUFFER_SIZE;

}
```

## Consumer

```
item next_consumed;

while (true)

{
    while (in == out)

        ; /* do nothing */

    next_consumed = buffer[out];

    out = (out + 1) % BUFFER_SIZE;
    /* consume the item in next
    consumed */

}
```

## ❖ Illustration of the problem:

Suppose that we wanted to provide a solution to the consumer-producer problem that fills **all** the buffers. We can do so by having an integer **counter** that keeps track of the number of full buffers. Initially, **counter** is set to 0. It is incremented by the producer after it produces a new buffer and is decremented by the consumer after it consumes a buffer.

# Bounded-Buffer – Producer & Consumer

```
item buffer[BUFFER_SIZE]; int in = 0; int out = 0;
```

## Producer

```
while (true) {  
    /* produce an item  
    in next produced */  
  
    while (counter == BUFFER_SIZE)  
        ; /* do nothing */  
  
    buffer[in] = next_produced;  
  
    in = (in + 1) % BUFFER_SIZE;  
  
    counter++;  
  
}
```

## Consumer

```
while (true) {  
    while (counter == 0)  
        ; /* do nothing */  
  
    next_consumed = buffer[out];  
  
    out = (out + 1) % BUFFER_SIZE;  
  
    counter--;  
  
    /* consume the item in next  
    consumed */  
  
}
```

# Race Condition

- ❖ **counter++** could be implemented as
- ❖ **counter--** could be implemented as

**registerA = counter**

**registerA = registerA + 1**

**counter = registerA**

**registerB = counter**

**registerB = registerB - 1**

**counter = registerB**

- ❖ Consider this execution interleaving with **count = 5** initially:

S0: producer execute <b>registerA</b>	<b>= counter</b>	{registerA = 5}
S1: producer execute <b>registerA</b>	<b>= registerA + 1</b>	{registerA = 6}
S2: consumer execute <b>registerB</b>	<b>= counter</b>	{registerB = 5}
S3: consumer execute <b>registerB</b>	<b>= registerB - 1</b>	{registerB = 4}
S4: producer execute <b>counter</b>	<b>= registerA</b>	{counter = 6}
S5: consumer execute <b>counter</b>	<b>= registerB</b>	{counter = 4}

# Critical Section Problem

- ❖ Consider system of  $n$  processes  $\{p_0, p_1, \dots, p_{n-1}\}$
- ❖ Each process has **critical section** segment of code
  - ❖ Process may be changing common variables, updating table, writing file, etc
  - ❖ When one process in critical section, no other may be in its critical section
- ❖ **Critical section problem** is to design protocol to solve this

# Critical Section

- ❖ Each process must ask permission to enter critical section in **entry section**, may follow critical section with **exit section**, then **remainder section**
- ❖ General structure of process **P**

```
do {  

entry section

  
    critical section  
  

exit section

  
    remainder section  
} while (true);
```

```
do {  
    while (turn == j);  
    critical section  
    turn = j;  
    remainder section  
} while (true);
```

# Solution to Critical-Section Problem

1. **Mutual Exclusion** - If process  $P_i$  is executing in its critical section, then no other processes can be executing in their critical sections
2. **Progress** - If no process is executing in its critical section and there exist some processes that wish to enter their critical section, then the selection of the processes that will enter the critical section next cannot be postponed indefinitely
3. **Bounded Waiting** - A bound must exist on the number of times that other processes are allowed to enter their critical sections after a process has made a request to enter its critical section and before that request is granted
  - ❖ Assume that each process executes at a nonzero speed
  - ❖ No assumption concerning **relative speed** of the  $n$  processes

# Peterson's Solution

- ❖ Applicable for two process solution
- ❖ Assume that the **load** and **store** machine-language instructions are atomic; that is, cannot be interrupted
- ❖ The two processes share two variables:
  - ❖ **int turn;**
  - ❖ **Boolean flag[2]**
- ❖ The variable **turn** indicates whose turn it is to enter the critical section
- ❖ The **flag** array is used to indicate if a process is ready to enter the critical section. **flag[i] = true** implies that process **P<sub>i</sub>** is ready!

# Peterson's Solution

Algorithm for Process  $P_i$

```
do {  
    flag[i] = true;  
    turn = j;  
    while (flag[j] && turn == j);
```

critical section

```
flag[i] = false;
```

remainder section

```
} while (true);
```

Algorithm for Process  $P_j$

```
do {  
    flag[j] = true;  
    turn = i;  
    while (flag[i] && turn == i);
```

critical section

```
flag[j] = false;
```

remainder section

```
} while (true);
```

# Peterson's Solution

- ❖ All three CS requirement are met:
  1. Mutual exclusion is preserved  
 $P_i$  enters CS only if:  
either **flag[j] = false** or **turn = i**
  2. Progress requirement is satisfied
  3. Bounded-waiting requirement is met

Algorithm for Process  $P_i$

```
do {  
    flag[i] = true;  
    turn = j;  
    while (flag[j] && turn == j);  
  
    critical section  
  
    flag[i] = false;  
  
    remainder section  
  
} while (true);
```

Thank You
